

For this lab, I used Claude Code as my main tool to build a portfolio website based on my resume and previous projects. The initial output was actually pretty solid in terms of layout. It created a clean structure with a hero section, project section, and contact area, which gave me a good starting point. However, the content it generated for my projects was very generic and didn't really reflect the actual work I had done in previous labs.

I had to go back and iterate a few times by prompting the AI to include more specific details about my projects, like the financial crisis prediction model and the FOMC sentiment analysis. Even then, some of the descriptions still felt vague, so I manually rewrote parts of them to better match what I actually did, including things like TF-IDF, clustering, and causal inference methods. This part definitely showed that while AI can generate structure quickly, it doesn't always capture the depth of the work without guidance.

There were also some technical things I had to fix on my own. For example, the AI didn't automatically link my projects to the correct GitHub repositories, so I had to manually add those links so the site would be functional. I also updated the project years to reflect when I actually completed the labs and adjusted the wording to sound more like my own writing instead of default AI phrasing.

Overall, Claude Code was really useful for getting a professional-looking site up quickly, especially since I don't have much experience with frontend development. At the same time, it definitely required multiple iterations and manual edits to make the site accurate and personalized. The biggest takeaway for me is that AI works best as a starting point, but you still need to step in and refine things if you want the final result to actually represent your work.
